

CS 536 Announcements for Wednesday, March 22, 2023

Programming Assignment 3 – due Thursday, March 23

Midterm 2 – Wednesday, March 29

Last Time

- review grammar transformations
- building a predictive parser
- FIRST and FOLLOW sets

Today

- review parse table construction
- predictive parsing and syntax-directed translation

Next Time

- static semantic analysis
- exam review

Recap of where we are

Predictive parser builds the parse tree top-down

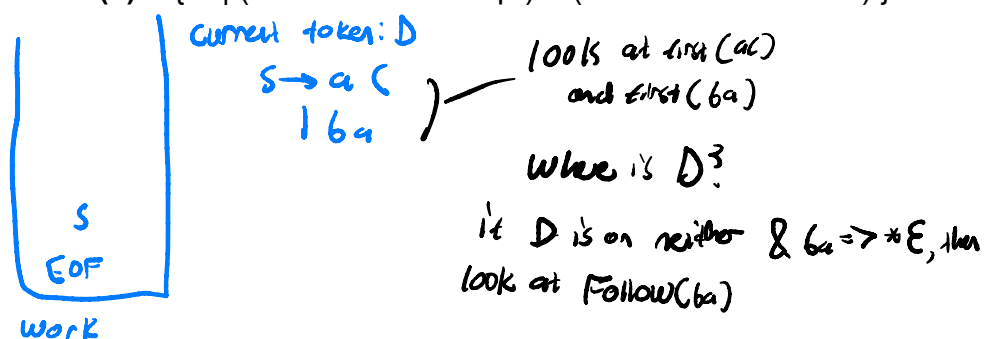

- 1 token lookahead
- parse/selector table
- stack tracking current parse tree's frontier

Building the parse table – given production $lhs \rightarrow rhs$, determine what terminals would lead us to choose that production

ie figure out T so that $table[lhs][T] = rhs$

$$FIRST(\alpha) = \{ T \mid (T \in \Sigma \wedge \alpha \Rightarrow^* T\beta) \vee (T = \epsilon \wedge \alpha \Rightarrow^* \epsilon) \}$$

$$FOLLOW(a) = \{ T \mid (T \in \Sigma \wedge s \Rightarrow^* aT\beta) \vee (T = EOF \wedge s \Rightarrow^* a) \}$$

FIRST and FOLLOW sets

FIRST(α) for $\alpha = y_1 y_2 \dots y_k$

Add FIRST(y_1) – { ϵ }

If ϵ is in FIRST($y_{1 \text{ to } i-1}$), add FIRST(y_i) – { ϵ }

If ϵ is in all RHS symbols, add ϵ

FOLLOW(a) for $x \rightarrow \alpha a \beta$

If a is the start, add EOF

Add FIRST(β) – { ϵ }

Add FOLLOW(x) if ϵ is in FIRST(β) or β is empty

Note that

FIRST sets

- only contain alphabet **terminals** and **ϵ**
- defined for arbitrary RHS and nonterminals
- constructed by started at the **beginning** of a production

FOLLOW sets

↳ at beginning of RHS (for first (LHS))

- only contain alphabet **terminals** and **EOF**
- defined for **nonterminals** only
- constructed by jumping into production

Putting it all together

- Build FIRST sets for each nonterminal
- Build FIRST sets for each production's RHS
- Build FOLLOW sets for each nonterminal
- Use FIRST and FOLLOW sets to fill parse table for each production

Building the parse table

```
for each production  $x \rightarrow \alpha$  {  
  for each terminal  $T$  in FIRST( $\alpha$ ) {  
    put  $\alpha$  in table[ $x$ ][ $T$ ]  
  }  
  if  $\epsilon$  is in FIRST( $\alpha$ ) {  
    for each terminal  $T$  in FOLLOW( $x$ ) {  
      put  $\alpha$  in table[ $x$ ][ $T$ ]  
    }  
  }  
}
```

Example

CFG

$s \rightarrow aC \mid ba$
 $a \rightarrow AB \mid Cs$
 $b \rightarrow D \mid \varepsilon$

FIRST and FOLLOW sets

	FIRST sets	FOLLOW sets
s	A, C, D	EOF, C
a	A, C	C, EOF
b	D, ε	A, C
$s \rightarrow aC$	A, C	
$s \rightarrow ba$	D, A, C	
$a \rightarrow AB$	A	
$a \rightarrow Cs$	C	
$b \rightarrow D$	D	
$b \rightarrow \varepsilon$	ε	

Parse table

for each production $x \rightarrow \alpha$

for each terminal T in $FIRST(\alpha)$
put α in $table[x][T]$

if ε is in $FIRST(\alpha)$

for each terminal T in $FOLLOW(x)$

put α in $table[x][T]$

because there's 2 \rightarrow not LCG

	A	B	C	D	EOF
s	aC, ba		aC, ba	ba	
a	AB		Cs		
b	ε		ε	D	

Example

CFG

$s \rightarrow (s) \mid \{s\} \mid \varepsilon$

FIRST and FOLLOW sets

	FIRST sets	FOLLOW sets
s	$(\{ \varepsilon$	$\{ \varepsilon \}$
$s \rightarrow (s)$	$($	
$s \rightarrow \{s\}$	$\{$	
$s \rightarrow \varepsilon$	ε	

Parse table

```

for each production  $x \rightarrow \alpha$ 
  for each terminal T in FIRST( $\alpha$ )
    put  $\alpha$  in table[x][T]

  if  $\varepsilon$  is in FIRST( $\alpha$ )
    for each terminal T in FOLLOW(x)
      put  $\alpha$  in table[x][T]
  
```

	()	{	}	EOF
s	(s)	ε	$\{s\}$	ε	ε

this is (L)

Parsing and syntax-directed translation

Recall syntax-directed translation (SDT)

To translate a sequence of tokens

- build the parse tree
- use translation rules to compute the translation of each non-terminal in the parse tree, bottom up
- the translation of the sequence is the translation of the parse tree's root non-terminal

Goal translation: evaluate expression

CFG:

expr \rightarrow expr + term
| term

term \rightarrow term * factor
| factor

factor \rightarrow INTLIT
| (expr)

SDT rules:

expr₁.trans = expr₂.trans + term.trans
expr.trans = term.trans

term₁.trans = term₂.trans * factor.trans
term.trans = factor.trans

factor.trans = INTLIT.value
factor.trans = expr.trans

The LL(1) parser never needed to explicitly build the parse tree
– it was implicitly tracked via the stack.

Instead of building parse tree, give parser a second, **semantic** stack
– *holds translations of nonterminals*

SDT **rules** are converted to **actions**

- Pop translations of RHS nonterms
- push computed translation of LHS nonterm

CFG:

expr \rightarrow expr + term
| term

term \rightarrow term * factor
| factor

factor \rightarrow INTLIT
| (expr)

SDT actions: right \rightarrow left

tTrans = pop; eTrans = pop; push(eTrans + tTrans)
~~x~~ tTrans = pop; push(tTrans)

fTrans = pop; tTrans = pop; push(tTrans * fTrans)
~~x~~ fTrans = pop; push(fTrans)

push(INTLIT.value)
~~x~~ eTrans = pop; push(eTrans)

uses rules

Parsing and syntax-directed translation (cont.)

Augment the parsing algorithm

- number the actions *(work)*
- when RHS of production is pushed onto symbol stack, include the actions
- when action is the top of symbol stack, pop & perform the action

CFG:

SDT actions:

```

expr  →  expr + term  #1  #1  tTrans = pop; eTrans = pop; push(eTrans + tTrans)
      |  term
term   →  term * factor  #2  #2  fTrans = pop; tTrans = pop; push(tTrans * fTrans)
      |  factor
factor →  #3  INTLIT      #3  push( INTLIT.value)
      |  ( expr )
  
```

Placing the action numbers in the productions

- action numbers go
 - after their corresponding non-terminals
 - before their corresponding terminal

if we're dealing with a terminal →
number before terminal

input: ... INTLIT(17) ...
 CFG:
 factor → INTLIT #3 #3 push(INTLIT.value)

Building the LL(1) parser

1) Define SDT using the original grammar

- write translation rules
- convert translation rules to actions that push/pop using semantic stack
- incorporate action #s into grammar rules

2) Transform grammar to LL(1)

- treating actions # like terminals

3) Compute FIRST and FOLLOW sets

- treat action #s like epsilon

4) Build the parse table

Example SDT on transformed grammar

Original CFG:

$\text{expr} \rightarrow \text{expr} + \text{term} \#1$
 $\quad \quad | \quad \text{term}$
 $\text{term} \rightarrow \text{term} * \text{factor} \#2$
 $\quad \quad | \quad \text{factor}$
 $\text{factor} \rightarrow \#3 \text{ INTLIT}$
 $\quad \quad | \quad (\text{expr})$

Transformed CFG:

$\text{expr} \rightarrow \text{term expr}'$
 $\text{expr}' \rightarrow + \text{term} \#1 \text{ expr}'$
 $\quad \quad | \quad \varepsilon$
 $\text{term} \rightarrow \text{factor term}'$
 $\text{term}' \rightarrow * \text{factor} \#2 \text{ term}'$
 $\quad \quad | \quad \varepsilon$
 $\text{factor} \rightarrow \#3 \text{ INTLIT} \mid (\text{expr})$

Transformed CFG:

$\text{expr} \rightarrow \text{term expr}'$
 $\text{expr}' \rightarrow + \text{term} \#1 \text{ expr}' \mid \varepsilon$
 $\text{term} \rightarrow \text{factor term}'$
 $\text{term}' \rightarrow * \text{factor} \#2 \text{ term}' \mid \varepsilon$
 $\text{factor} \rightarrow \#3 \text{ INTLIT} \mid (\text{expr})$

SDT actions:

$\#1 : \text{tTrans} = \text{pop};$
 $\quad \text{eTrans} = \text{pop};$
 $\quad \text{push}(\text{eTrans} + \text{tTrans})$
 $\#2 : \text{fTrans} = \text{pop};$
 $\quad \text{tTrans} = \text{pop};$
 $\quad \text{push}(\text{tTrans} * \text{fTrans})$
 $\#3 : \text{push}(\text{INTLIT.val})$

Parse table

	+	*	()	INTLIT	EOF
expr			term expr'		term expr'	
expr'	+ term #1 expr'			ε		ε
term			factor term'		factor term'	
term'	ε	* factor #2 term'		ε		ε
factor			(expr)		#3 INTLIT	

Input: #3 * 2 EOF
 ↑ ↑ ↑ ↑ ↑
 $\#3 \text{ factor} \#2 \text{ term}'$
 $\text{ET} = 2 \rightarrow 6$
 $\text{LT} = 3$
 $\text{LT} = 6 \rightarrow 11 \text{ (6+6)}$
 $\text{et} = 5$

What about ASTs?

Push and pop AST nodes on the semantic stack

Keep references to nodes that we pop

Original CFG:

$$\text{expr} \rightarrow \text{expr} + \text{term} \#1$$
$$| \text{term}$$

term → #2 INTLIT

Transformed CFG:

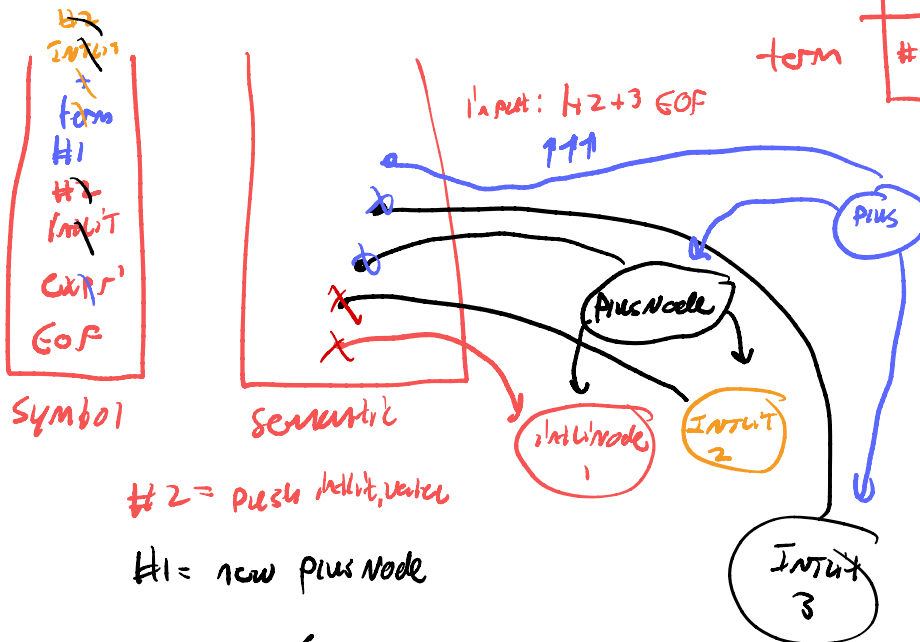

$$\begin{array}{ll} \text{expr} & \rightarrow \text{term expr}' \\ \text{expr}' & \rightarrow + \text{term \#1 expr}' \\ & \mid \varepsilon \\ \text{term} & \rightarrow \text{\#2 INTLIT} \end{array}$$

SDT actions:

```
#1 : tTrans = pop;
    eTrans = pop;
    push( new PlusNode(eTrans, tTrans))
#2 : push( new InitNode(INITIAL_VALUE))
```

Parse table:

	START	+	EOF
expr	term expr'		
expr'		+ term #1 expr	ϵ
term	#2 INTUIT		

#2 = push deliv, vector

H1 = new plus node

✓ } EOF

#1 \rightarrow odd

Or...

Associativity
Restored!
